THE HAZARD CANNOT BE STOPPED. THE DISASTER CAN.

The five years from 2020 to 2024 were the warmest ever measured. In 1970 a cyclone killed up to half a million people in the Bengal delta. In 2020 a storm of comparable strength hit the same coast: more than two million people were moved to safety first, and the death toll was in the dozens.

This book is about that gap. Two decades of climate records, read closely, show why the next disaster will devastate some places and barely touch others — and why the difference is almost always a decision rather than a fate. Heat, flood, drought, fire, food, water, migration, conflict: every chapter ends by naming the observation that would prove it wrong.

Twenty-four chapters. Twenty-five data tables. Eleven figures. Twenty-four case studies. One hundred and forty-five sources. Written for readers who want the evidence, not the slogan.

- Why a cyclone killed up to 500,000 people in 1970 and dozens in 2020 on the same coastline
- The heatwave that killed 70,000 Europeans in 2003 — and the hotter one that killed 61,700 in 2022
- The Ahr valley, where the forecast was right and 180 people died anyway
- What a heat action plan, a shelter register and a protected budget line actually cost
- The four clocks of climate policy: emissions, concentration, temperature, sea level
- How to read a death toll, a loss estimate and a warning that never reached its street

A prepared world is not a world without disasters. It is a world in which the same event kills fewer people.

Start with the last pages: five questions that turn this book into a plan for your own street.

Setyo Wisodo holds a degree in history education from Universitas Negeri Malang. He reads the past for patterns, tests them against present-day data, and writes about what that comparison implies for disaster risk adaptation and community resilience.
